Temporal networks described by *temporal quantities* (TQs) were introduced in the paper [1]. We get a *temporal network* $\mathcal{N}_{\mathcal{T}} = (\mathcal{V}, \mathcal{L}, \mathcal{T}, \mathcal{P}, \mathcal{W})$ by attaching the *time* \mathcal{T} to an ordinary network, where $\mathcal{T} = [T_{min}, T_{max})$ is a linearly ordered set of time points $t \in \mathcal{T}$ which are usually integers or reals.

In a temporal network nodes/links activity/presence, nodes properties, and links weights can change through time. These changes are described with TQs. A TQ is described by a sequence

$$\mathbf{a} = [(s_r, f_r, v_r) : r = 1, 2, \dots, k]$$

where $[s_r, f_r)$ determines a time interval and v_r is the value of the TQ \mathbf{a} on this interval. The set $T_a = \bigcup_r [s_r, f_r)$ is called the *activity set* of \mathbf{a} . For $t \notin T_a$ its value is *undefined*, $a(t) = \mathfrak{K}$. Assuming $a + \mathfrak{K} = \mathfrak{K} + a = a$ and $a \cdot \mathfrak{K} = \mathfrak{K} \cdot a = \mathfrak{K}$ we can extend the addition and multiplication to TQs

$$\begin{aligned} (a + b)(t) &= a(t) + b(t) & \text{and} & & T_{a+b} &= T_a \cup T_b \\ (a \cdot b)(t) &= a(t) \cdot b(t) & \text{and} & & T_{a \cdot b} &= T_a \cap T_b \end{aligned}$$

$a + b :$

$a :$

$a = [(1, 5, 2), (6, 8, 1),$
 $(11, 12, 3), (14, 16, 2),$
 $(17, 18, 5), (19, 20, 1)]$

$b :$

$b = [(2, 3, 4), (4, 7, 3),$
 $(9, 10, 2), (13, 15, 5),$
 $(16, 21, 1)]$

$a \cdot b :$

Let $T_V(v) \subseteq \mathcal{T}$, $T_V \in \mathcal{P}$, be the activity set for a node $v \in \mathcal{V}$ and $T_L(\ell) \subseteq \mathcal{T}$, $T_L \in \mathcal{W}$, the activity set for a link $\ell \in \mathcal{L}$. The following *consistency condition* must be fulfilled for activity sets: If a link $\ell(u, v)$ is active at the time point t then its end-nodes u and v should be active at the time point t :

$$T_L(\ell(u, v)) \subseteq T_V(u) \cap T_V(v).$$

In the following we will need

- *Total* $\text{total}(a) = \sum_i (f_i - s_i) \cdot v_i$
- *Average* $\text{average}(a) = \frac{\text{total}(a)}{|T_a|}$
- *Maximum* $\max(a) = \max_i v_i$

To support the computations with TQs we developed in Python a library TQ [1].

Traditional generalized blockmodeling scheme

A *blockmodel* (BM) [7] consists of structures obtained by identifying all units from the same cluster of the clustering / *partition* \mathbf{C} , $\pi(v) = i \Leftrightarrow v \in C_i$. For an exact definition of a blockmodel we have to be precise also about which blocks produce an arc in the *reduced graph* and which do not, what is the *weight* of this arc, and in the case of generalized BM, of what *type*. The reduced graph can be represented by relational matrix, called also *image matrix*.

To the traditional BM scheme we add the time dimension – the BM partition π is described for each node v with a temporal quantity $\pi(v, t)$: $\pi(v, t) = i$ means that in time t node v belongs to cluster i . The structure and activity of clusters $C_i(t) = \{v : \pi(v, t) = i\}$ can change through time, but they preserve their identity.

For the BM μ the clusters are mapped into BM nodes $\mu : C_i \rightarrow [i]$. To determine the BM we still have to specify how the links from C_i to C_j are represented in the BM – in general, for the model arc $([i], [j])$, we have to specify two TQs: its weight $a_{ij}(t)$ and, in the case of generalized BM, its type $\tau_{ij}(t)$. The weight can be an object of a different type than the weights of the block links in the original temporal network.

[3]

We assume that in a temporal network $\mathcal{N} = (\mathcal{V}, \mathcal{L}, \mathcal{T}, \mathcal{P}, \mathcal{W})$ the links weight is described by a TQ $w \in \mathcal{W}$. In the following years we intend to develop methods case by case.

- constant partition – nodes stay in the same cluster all the time
 - Sunbelt 2020: indirect approach based on clustering of TQs: $p(v) = \sum_{u \in N(v)} w(v, u)$, hierarchical clustering and leaders [5];
 - EUSN 2021: indirect approach by conversion to the **clustering with relation constraint** (CRC);
 - local optimization of the criterion function P over Φ
- dynamic partition – nodes can move between clusters through time. The details are still to be elaborated.

To use the clustering in the construction of a nodes partition we have to define a similarity (or dissimilarity) measure $s(u, v)$ between nodes. An obvious solution is $s(u, v) = f(w(u, v))$, for example

- Total activity $s_1(u, v) = \text{total}(w(u, v))$
- Average activity $s_2(u, v) = \text{average}(w(u, v))$
- Maximal activity $s_3(u, v) = \max(w(u, v))$

We can transform a similarity $s(u, v)$ into a dissimilarity by

$$d(u, v) = \frac{1}{s(u, v)}$$

We transformed the partitioning problem to the clustering with relational constraint problem.

ClusTQ at <https://github.com/bavla/TQ> .

- 1 Using clustering with relational constraint determine the partition π
- 2 Construct the corresponding BM
- 3 Interpret the BM

The simplest option is to take for \mathbf{a}_{ij} the sum of all total activities of links from C_i to C_j .

Another option is to consider the activity of links from C_i to C_j as a TQ

$$\mathbf{a}_{ij} = \sum_{\ell \in \mathcal{L}(C_i, C_j)} w(\ell)$$

September 11th Reuters terror news

Blockmodeling

Introduction

BM and CRC

Example

Conclusions

References

The Reuters terror news network was obtained from the CRA (Centering Resonance Analysis) networks produced by Steve Corman and Kevin Dooley at Arizona State University. The network is based on all the stories released during 66 consecutive days by the news agency Reuters concerning the September 11 attack on the U.S., beginning at 9:00 AM EST 9/11/01.

The nodes, $n = 13332$, of this network are important words (terms). For a given day, there is an edge between two words iff they appear in the same utterance (for details see the paper [6]). The weight of an edge is its frequency. There are no loops in the network.

As an example we will analyze the subnetwork of 50 the most active terms available as **Terror50.json**.

The network Terror50 is undirected – so will be also the BM.
